Received: date / Accepted: date

#### Abstract

Given an undirected graph, the Minimum Stretch Spanning Tree Problem (MSSTP) deals with finding a spanning tree such that the maximum distance in the tree for adjacent nodes in the original graph, called the stretch, is minimum. This is an NP-hard problem with many applications in transportation and communication networks. We propose a General Variable Neighborhood Search (GVNS) algorithm based on a balance between solution generation and improvement. To achieve this balance, we consider different construction heuristics and neighborhood strategies to efficiently explore the search space. To assess the merit of our proposal, we perform extensive experimentation on various classes of graphs consisting of 214 instances. A comparison in terms of solution quality and execution time with the best previous method, namely an Artificial Bee Colony (ABC) algorithm, shows the superiority of GVNS. Results are compared using statistical tests to draw significant conclusions.

Keywords General Variable Neighborhood Search • Artificial Bee Colony • Spanning trees • Minimum Stretch Spanning Tree Problem

## 1 Introduction

Minimum Stretch Spanning Tree Problem (MSSTP) is based on two wellknown problems, finding a spanning tree of a given graph, and finding a shortest path between pairs of nodes in a graph. The former has significance in

networking problems $[1,2,3]$ whereas the latter is relevant in operations research, transportation, and VLSI design [4, 5, 6, 7]. A spanning tree of a graph is a subgraph that includes all the vertices in the original graph and is a tree (i.e., a connected acyclic graph). The MSSTP consists of finding a spanning tree of a graph in which the maximum distance in the tree for adjacent nodes in the original graph is minimized.

Given an undirected connected graph $G=(N, A)$, where $N$ is the set of nodes, with $|N|=n$, and $A \subseteq\{(u, w): u, w \in N\}$ is the set of arcs, the MSSTP is formally defined as follows:

Let

$$
\Theta(G)=\left\{S_{-} T: S_{-} T \text { is spanning tree of } G\right\}
$$

Then, MSSTP consists in finding a spanning tree $S_{-} T^{*} \in \Theta(G)$ such that

$$
\operatorname{Stretch}\left(G, S_{-} T^{*}\right)=\min _{\forall S_{-} T \in \Theta(G)}\left\{\operatorname{Stretch}\left(G, S_{-} T\right)\right\}
$$

where,

$$
\operatorname{Stretch}\left(G, S_{-} T\right)=\max _{\forall(u, w) \in A} D_{S_{-} T}(u, w)
$$

and $D_{S_{-} T}(u, w)$ is the distance (path length) between $u$ and $w$ in $S_{-} T$.
Let $(u, w) \in A$, then a path between the nodes $u$ and $w$ in $S \_T$ is critical if $D_{S_{-} T}(u, w)$ is maximum over all pairs of adjacent nodes of $G$; i.e., $D_{S_{-} T}(u, w)$ $=\operatorname{Stretch}\left(G, S_{-} T\right)$. Note that a spanning tree can have more than one critical path. Throughout this paper, a solution $S_{-} T$ to the problem is a spanning tree of the input graph $G$, and $\operatorname{Stretch}\left(S_{-} T\right)$ or simply Stretch refers to its objective value.

Fig. 1 Stretch in spanning tree $S_{-} T$ of a graph $G$

Figure 1 shows the $S t r e t c h$ in the spanning tree $S_{-} T$ of a given graph $G$. Here, $D_{S_{-} T}(1,4)=3, D_{S_{-} T}(2,6)=2, D_{S_{-} T}(3,4)=5, D_{S_{-} T}(5,8)=2$ and for the remaining arcs of $G$ it is 1 . Since the $S$ tretch is the maximum distance between two adjacent nodes in $G$, then in this example the Stretch $=5$, and the critical path is $(3,2,1,8,7,4)$ (shown with green color arcs).

It is worth to mention that the MSSTP is a particular case of the tree $t$-spanner problem, which involves arc weighted graphs. This problem has applications in various areas such as distributed systems, parallel machine architectures, and communication networks [9]. As an example [10], consider a distributed network of processors in which it is required to route a message between any two processors. This system can be represented as a graph by considering the processors in a network as nodes and the links between them as arcs. As one of the factors on which the cost of routing a message depends is number of arcs between the source and destination, the length of the path (number of arcs) along which the messages traverse has to be minimized. Finding an optimal solution to this problem becomes too expensive for large sized systems. Hence, the problem is to find an efficient routing scheme for large scale communication networks such that the routing cost is minimum. The efficiency of a routing scheme can be measured in terms of the stretch factor, which can be defined as the maximum ratio between the length produced by the routing scheme and the shortest path between the two processors.

The tree $t$-spanner problem has been extensively studied, but only a few approaches are proposed for the MSSTP. The tree $t$-spanner was initially defined for constructing network synchronizers [16] in distributed systems, network design and communication networks [17]. Graph theoretic, algorithmic and complexity issues pertaining to tree spanners are studied in [18], and a mixed integer programming formulations with a branch and cut in [19]. In terms of metaheuristics, we can find a Genetic Algorithm (GA) and an ABC algorithm for the weighted tree $t$-spanner problem [9], where the ABC obtains better results than the GA. Thus, we adapted this ABC for the MSSTP to compare our algorithm over a wide spectrum of instances.

It is a well established area of research in many optimization problems to find optimal solutions for special classes of graphs. That is also the case of the MSSTP, where optimal results have been proved for some specific graphs, such as Peterson graph, complete $k$-partite graphs, split graphs and rectangular grids [23]. A recent addition to this work includes optimal results for hypercubes, cartesian product of different classes of graphs, hamming graphs and higher-dimensional grids [24, 25]. Some approximation algorithms have also been developed for the problem. In [26], an algorithm which computes a spanning tree with Stretch $O\left(o p t^{4}\right)$ in time $O(n \log n)$ is developed for the special case of grids and unit disk graphs. However, the scope of our approach is completely different. In particular, we develop a general solving method that can be applied to any instance of this NP-hard problem. Our approach is based on a well-known metaheuristic methodology, the GVNS [27]. This method is based on its efficient search of the solution space in changing the pre-defined neighborhoods in a systematic manner [12]. To the best of our knowledge no other metaheuristic for general graphs has been previously proposed for the MSSTP.

The contribution of this paper is twofold, since we propose a heuristic to outperform the best previous method, and we also propose alternative designs to learn about search strategies in the context of graph problems. In partic-
ular, some spanning tree generating procedures are adapted to the MSSTP which serve as the five construction heuristics for generating initial solutions. The VNS metaheuristic is primarily based on a systematic exploration and exploitation of neighborhoods, therefore strategies balancing between diversification and intensification are developed which form our six different neighborhoods.

The remaining paper is organized as follows. Section 2 presents the proposed GVNS and implementation details of its components for MSSTP. The adapted version of ABC algorithm for MSSTP is given in Section 3. The results obtained by GVNS algorithm and two variants of the ABC algorithm for MSSTP over a large range of graphs have been discussed in Section 4. Section 5 provides the conclusions of the paper.

## 2 General Variable Neighborhood Search

The GVNS proposed for the MSSTP is sketched in Algorithm 1. It starts by generating an initial solution $S \_T$ (Step 2) using a construction heuristic described in Section 2.1. The $S_{-} T_{\text {best }}$ maintains the best solution found at any step of the algorithm. Step 7 performs the Shake procedure. It is done by randomly generating a neighbor $S_{-} T^{\prime}$ of $S_{-} T$ in $\mathrm{NBHD}_{i}$ (described in Section 2.2) of $S_{-} T$. In Step 8, a local minimum solution $S_{-} T^{\prime \prime}$ is obtained from $S_{-} T^{\prime}$ using the Variable Neighborhood Descent (B-VND) method [11]. $S_{-} T_{\text {best }}$ is updated if the Stretch of $S_{-} T^{\prime \prime}$ is better than that of $S_{-} T_{\text {best }}$ (Steps 9-11). Now, Stretch of the two solutions $S_{-} T$ and $S_{-} T^{\prime \prime}$ are compared (Step 12) and $S_{-} T$ is replaced with $S_{-} T^{\prime \prime}$ if it improves $S_{-} T$ (Step 13). In this case, $i$ is set to 1 (Step 14) i.e. the new solution will be explored starting again with the first neighborhood. If $S_{-} T^{\prime \prime}$ fails to improve $S_{-} T$ in the current neighborhood, then the search is moved to the next neighborhood (Step 16). Steps 7-17 are repeated until all the neighborhoods ( 1 to $n b d_{\max }$ ) are explored. The search continues until the stopping criterion is met i.e. iter $_{\text {init }}$ reaches the maximum number of iterations iter $_{\text {max }}$. We refer the reader to the excellent chapters on VNS [28] and VND [29] in the Handbook of Heuristics [30] for a detailed description about these two methodologies.

Algorithm 2 outlines the procedure B-VND used in GVNS to find a local minimum after exploring all the neighborhoods of a given solution. It starts by finding a best neighbor $S_{-} T_{1}^{\prime}$ of solution $S_{-} T_{1}$ in its $j$-th neighborhood using the function Find_Best_Nbr (Step 3). Then, neighborhood is changed accordingly by comparing the solutions $S_{-} T_{1}$ and $S_{-} T_{1}^{\prime}$ (Steps 4-9). $S_{-} T_{1}$ keeps improving in a similar way until all the neighborhoods of $S_{-} T_{1}$ are explored.

Algorithm 3 presents the function Find_Best_Nbr used in B-VND. In Steps $5-13$, neighbor $S_{-} T_{2}^{\prime \prime}$ of the solution $S_{-} T_{2}$ in the neighborhood $\mathrm{NBHD}_{k}$ is generated. If $S_{-} T_{2}^{\prime \prime}$ improves $S_{-} T_{2}$ then $S_{-} T_{2}^{\prime \prime}$ replaces $S_{-} T_{2}$ and the process is repeated in this neighborhood. If no improvement is there then the last obtained solution is compared with the original one. This original solution is replaced by a better solution. The process (Steps 4 to 19) is repeated until no

            \(S_{-} T_{1} \leftarrow S_{-} T_{1}^{\prime}\)
            \(j \leftarrow 1\)
        else
            \(j \leftarrow j+1\)
        end if
    end while
    return \(S_{-} T_{1}\)
```

further improvement is obtained. The different construction heuristics and the neighborhood strategies used in GVNS are discussed below.

### 2.1 Initial Solution Generation

The initial solution is generated using a construction heuristic selected randomly from the five construction heuristics namely-

- Random_Prim
- Random_Kruskal
- Random_Dijkstra's
- Max_degree_BFS
- Random_BFS

```
Algorithm 3 Find_Best_Nbr \(\left(S_{-} T_{2}, k\right)\)
    flag \(_{1} \leftarrow 0\)
    flag \(_{2} \leftarrow 0\)
    while flag \(_{1} \neq 1\) do
        \(S_{-} T_{2}^{\prime} \leftarrow S_{-} T_{2}\)
        while flag \(_{2} \neq 1\) do
            \(S_{-} T_{2}^{\prime \prime} \leftarrow \operatorname{NBHD}_{k}\left(S_{-} T_{2}\right)\)
            if \(\operatorname{Stretch}\left(S \_T_{2}^{\prime \prime}\right)<\operatorname{Stretch}\left(S \_T_{2}\right)\) then
                \(S_{-} T_{2} \leftarrow S \_T_{2}^{\prime \prime}\)
                flag \(_{2} \leftarrow 0\)
            else
                flag \(_{2} \leftarrow 1\)
            end if
        end while
        if \(\operatorname{Stretch}\left(S_{-} T_{2}\right)<\operatorname{Stretch}\left(S_{-} T_{2}^{\prime}\right)\) then
            flag \(_{1} \leftarrow 0\)
            flag \(_{2} \leftarrow 0\)
        else
            flag \(_{1} \leftarrow 1\)
        end if
    end while
    return \(S_{-} T_{2}^{\prime}\)
```

Random_Prim (described in Section 3), Random_Kruskal and Random_Dijkstra's construct spanning tree using well known Prim's, Kruskal's and Dijkstra's algorithms [8] respectively by selecting arcs randomly and considering the unit weights on the arcs. The other two heuristics Max_degree_BFS and Random_BFS produce spanning trees using the well known Breadth First Search (BFS) algorithm. Max_degree_BFS explores all the nodes of the graph starting from a maximum degree node as root. The neighbor nodes are also traversed in decreasing order of their degrees. The process continues until all nodes are traversed. Preferring higher degree nodes helps in keeping the neighbors close and hence may lead to a spanning tree with lower Stretch. In Random_BFS a spanning tree is produced by visiting neighbors randomly.

### 2.2 Neighborhood Strategies

We have designed six neighborhood strategies for generating a neighbor of a given solution as detailed below.

1. Method $1\left(\mathrm{NBHD}_{1}\right)$ : In this method neighbors of solutions are generated based on the cycle exchange. An arc $(u, w) \in A(\mathrm{G}) \backslash A\left(S_{-} T\right)$ is randomly selected, and added to $S \_T$ creating a cycle $C y c$. Now, $\left(u^{\prime}, w^{\prime}\right) \in C y c \backslash(u, w)$ is picked up randomly and removed from $C y c$ resulting in a neighbor $S_{-} T^{\prime}$. This method helps in diversification as the arcs to be added and deleted are chosen randomly (see Algorithm 4).
Figure 2 illustrates this process. An arc $(4,6)$ belonging to $G$ is added to its spanning tree $S_{-} T$ which forms a cycle in $S_{-} T$. Now the arc $(4,7)$ appearing in this cycle is removed from $S_{-} T$ producing a neighbor $S_{-} T^{\prime}$.
```
Algorithm 4 NBHD \(_{1}\left(S \_T\right)\)
    select \((u, w)\) randomly from \(A(G) \backslash A\left(S_{-} T\right)\)
    \(S \_T \leftarrow S \_T \cup(u, w)\)
    \(C y c \leftarrow\) cycle obtained by adding arc \((u, w)\) to \(S \_T\)
    \(\left(u^{\prime}, w^{\prime}\right) \leftarrow\) select randomly such that \(\left(u^{\prime}, w^{\prime}\right) \in A(C y c)\)
    \(S \_T^{\prime} \leftarrow S \_T \backslash\left(u^{\prime}, w^{\prime}\right)\)
    return \(S_{-} T^{\prime}\)
```

G
(a)

Fig. 2 (a) Graph $G$ and its (b) Spanning tree $S_{-} T$ with its neighbor $S_{-} T^{\prime}$ obtained from $\mathrm{NBHD}_{1}$
2. Method $2\left(\mathrm{NBHD}_{2}\right)$ : This method generates a neighbor of a spanning tree by replacing one of its subtree with another subtree of the graph (see Algorithm 5). Initially, a critical path $C_{-} P$ in $S_{-} T$ is randomly selected and a subgraph $G^{\prime}$ of $G$ induced by the nodes of $C_{-} P$ is formed. A spanning tree $P \_T$ of $G^{\prime}$ is then generated using the heuristic Random_Prim described in Section 2.1. Now with the help of partial tree $P_{-} T$ and the given $S_{-} T$, a neighbor $S_{-} T^{\prime}$ is obtained by adding those arcs of $S_{-} T$ to $P_{-} T$ which are not in $C_{-} P$. This method favors the intensification as one of the critical paths is chosen for the replacement and hence may provide an improved solution.

This procedure is illustrated in Fig. 3. $S_{-} T$ in Fig. 3 (a) shows a spanning tree of $G$ in Fig. 2 (a) which has a critical path $\{(5,8,1,6,4,7)$ corresponding to Stretch 5 . Now, this path (shown with green color arcs) is selected and a subgraph $G^{\prime}$ of $G$ is produced from its nodes. A spanning tree $P_{-} T$ of $G^{\prime}$ is created using Random_Prim. This $P_{-} T$ is transformed into a complete spanning tree $S_{-} T^{\prime}$ by adding those arcs (shown with the green color dotted lines) to it from $S_{-} T$ which are not in ( $5,8,1,6,4,7$ ).

```
Algorithm \(5 \mathrm{NBHD}_{2}\left(S \_T\right)\)
    \(C_{-} P \leftarrow\) critical path in \(S_{-} T\) selected randomly
    \(N^{\prime} \leftarrow\) nodes in \(C_{-} P\)
    \(A\left(C_{-} P\right) \leftarrow \operatorname{arcs}\) in \(C_{-} P\)
    \(G^{\prime} \leftarrow\) subgraph of \(G\) with node set \(N^{\prime}\)
    \(P \_T \leftarrow\) spanning tree of \(G^{\prime}\) generated using Random_Prim
    \(S_{-} T^{\prime} \leftarrow P_{-} T \cup\left\{(u, w):(u, w) \in A\left(S_{-} T\right) \backslash A\left(C_{-} P\right)\right\}\)
    return \(S_{-} T^{\prime}\)
```

The remaining methods $\mathrm{NBHD}_{3}$ to $\mathrm{NBHD}_{6}$ are similar to $\mathrm{NBHD}_{2}$, where the partial tree $P_{-} T$ is generated using the heuristics Random_Kruskal, Random_Dijkstra's, Max_degree_BFS and Random_BFS respectively.

## 3 Artificial Bee Colony Algorithm for MSSTP

The ABC algorithm is the best heuristic identified in the related literature for tree $t$-spanner problem [9]. We therefore adapted it to the MSSTP. The basic framework of ABC is inspired from the intelligent foraging behaviour of honey bees. Based on their behaviour, the bees are divided into three categories: employed bees, onlooker bees and scout bees. The solutions of the initial population $\left(p o p_{\text {employed }}\right)$ refers to the food sources whereas the fitness (quality) of these solutions refer to the nectar amount of the respective food sources. Now these food sources are exploited by generating neighbors with the help of employed bees. The role of onlooker bees is to further exploit those food sources which are rich in nectar amount in order to find the better food sources (the ones containing more nectar). If a food source is not improved by the employed bee for a fixed number of iterations, then it is replaced by a new food source found by the scout bee.

In the context of MSSTP, we first describe the solution generation method followed by the neighborhood strategies of [9]. For a fairer comparison, we have used the strategies of [9] for these two procedures. Prim's algorithm [31] is adapted to construct a solution by selecting arcs randomly rather than choosing them according to their weights. Two neighborhoods $n b d_{1}$ and $n b d_{2}$ are adapted suitably to locally improve a given solution based on a set of arcs $A_{c}$ in the critical path. Note that a path from $u$ to $w$ is critical in the case of tree $t$-spanner problem if $t=$ Stretch_Factor $^{\left(G, S \_T\right)}$ whereas for MSSTP, the critical path is as defined in Section 1.

Stretch $=5$

(a)

(b)

Fig. 3 (a) Spanning tree $S_{-} T$ of $G$ in Fig. 2 (a) and its (b) subgraph $G^{\prime}$ induced by the vertex set of critical path $C_{-} P$ and its spanning tree $P_{-} T$ obtained using Random_Prim, (c) neighbor $S_{-} T^{\prime}$ of $S_{-} T$ obtained from $S_{-} T$ and $P_{-} T$ using NBHD ${ }_{2}$

The first local search method is based on the neighborhood $n b d_{1}$ (see Algorithm 6) in which first an arc $(u, w) \in A_{c}$ from a solution $S_{-} T_{1}$ is deleted resulting in two disconnected components of $S_{-} T_{1}$. Then, a neighbor $S_{-} T_{1}^{\prime}$ is produced by joining these components together. For this another solution $S_{-} T_{2}$ is selected randomly from the population and an arc from $S_{-} T_{2}$, which can join
the two components, is found by checking all the arcs iteratively. In the absence of such an arc in $S_{-} T_{2}$, the process is repeated with another solution $S_{-} T_{2}$ of the population. The second local search method, contrasts with the first one in the way in which the two disconnected components are reconnected. The arcs required for this purpose are picked up from the graph $G$ resulting in a better exploitation of the neighborhood ( $n b d_{2}$ in this case).

```
Algorithm 6 nbd \(_{1}\left(S_{-} T_{1}\right)\)
    \(C_{-} P \leftarrow\) critical path in \(S_{-} T_{1}\) selected randomly
    \(A_{c} \leftarrow\) arcs in \(C_{-} P\)
    Select an \(\operatorname{arc}(u, w) \in A_{c}\) randomly
    \(\left[P_{-} T_{1}, P_{-} T_{2}\right] \leftarrow\left\{\left(u_{1}, w_{1}\right):\left(u_{1}, w_{1}\right) \in A\left(S_{-} T_{1}\right) \backslash(u, w)\right\}\)
    joined \(\leftarrow 0\)
    while joined \(\neq 1\) do
        \(S_{-} T_{2} \leftarrow\) select a solution \(\in\) pop \(_{\text {employed }}\) randomly
        for each arc \(\left(u^{\prime}, w^{\prime}\right) \in S_{-} T_{2}\) do
            if \(\left(u^{\prime}, w^{\prime}\right)\) can join \(P_{-} T_{1}\) and \(P_{-} T_{2}\) then
                \(S \_T_{1}^{\prime} \leftarrow P \_T_{1} \cup P \_T_{2} \cup\left(u^{\prime}, w^{\prime}\right)\)
                joined \(\leftarrow 1\)
            end if
        end for
    end while
    return \(S_{-} T_{1}^{\prime}\)
```

In the ABC procedure (outlined in Algorithm 7), Prim's algorithm is used to generate $m_{1}$ number of initial solutions. Each solution of the population is referred as an employed bee. For the iterative procedure, neighbor of a solution is obtained by probabilistically selecting one of the local search methods. If neighbour is better, it replaces the original solution. If after iter $_{\text {limit }}$ number of iterations, the solution does not improve then the scout bee produces a new solution which is used to replace the non-improving solution. A Binary Tournament Selection method (which picks a solution with better fitness from the two randomly selected solutions) is used to select $m_{2}$ solutions (acting as onlooker bees) out of $m_{1}$ solutions of the population with a probability $P_{b t s}$. This is done with an objective to further exploit their neighborhoods using the two neighborhood strategies of [9]. The complete procedure is repeated until the termination criterion is met.

For further impartial comparison of GVNS with the ABC approach, we also implemented $A B C$ with the neighborhood strategies used in GVNS. We refer this version as ABC_Nbr.

## 4 Experimental Results and Analysis

The two main objectives of our experimentation consist of investigating different search strategies, and then comparing the performance of the three algorithms ABC, ABC_Nbr and GVNS for MSSTP in terms of solution quality

```
Algorithm 7 Artificial Bee Colony Algorithm for MSSTP (ABC)
    pop \(p_{\text {employed }} \leftarrow\) generate initial solutions \(S_{-} T_{i}, i=1\) to \(m_{1}\) using Prim's algorithm
    \(S \_T_{\text {best }} \leftarrow\) best solution of pop \(_{\text {employed }}\)
    while termination criterion is not met do
        for \(i=1\) to \(m_{1}\) do
            if \(\rho<P_{n b d}\) then
                    \(S_{-} T_{i}^{\prime} \leftarrow n b d_{1}\left(S_{-} T_{i}\right)\)
            else
                \(S_{-} T_{i}^{\prime} \leftarrow n b d_{2}\left(S_{-} T_{i}\right)\)
            end if
            if \(\operatorname{Stretch}\left(S_{-} T_{i}^{\prime}\right)<\operatorname{Stretch}\left(S_{-} T_{i}\right)\) then
                    \(S_{-} T_{i} \leftarrow S_{-} T_{i}^{\prime}\)
            else
                if \(S_{-} T_{i}\) does not improve till iter \(_{l_{i m i t}}\) then
                    \(S_{-} T_{\text {scout }} \leftarrow\) generate solution using Prim's algorithm
                    \(S \_T_{i} \leftarrow S \_T_{\text {scout }}\)
                end if
            end if
            if \(\operatorname{Stretch}\left(S_{-} T_{i}\right)<\operatorname{Stretch}\left(S_{-} T_{\text {best }}\right)\) then
                \(S_{-} T_{\text {best }} \leftarrow S_{-} T_{i}\)
            end if
        end for
        for \(i=1\) to \(m_{2}\) do
            \(S_{-} T_{o_{i}} \leftarrow\) select solution from pop \(p_{\text {employed }}\) using Binary Tournament selection
    method
            if \(\rho<P_{n b d}\) then
                \(S_{-} T_{\text {onlooker }_{i}} \leftarrow n b d_{1}\left(S_{-} T_{o_{i}}\right)\)
            else
                \(S \_T_{\text {onlooker }_{i}} \leftarrow n b d_{2}\left(S_{-} T_{o_{i}}\right)\)
            end if
        end for
        for \(i=1\) to \(m_{2}\) do
            if \(\operatorname{Stretch}\left(S_{-} T_{\text {onlooker }_{i}}\right)<\operatorname{Stretch}\left(S_{-} T_{o_{i}}\right)\) then
            \(S_{-} T_{o_{i}} \leftarrow S_{-} T_{\text {onlooker }_{i}}\)
            end if
            if \(\operatorname{Stretch}\left(S_{-} T_{\text {onlooker }_{i}}\right)<\operatorname{Stretch}\left(S_{-} T_{\text {best }}\right)\) then
                \(S \_T_{\text {best }} \leftarrow S_{-} T_{\text {onlooker }_{i}}\)

and running time. The three algorithms are implemented in $\mathrm{C}++$ on ubuntu 16.04 LTS machine with $\operatorname{Intel}(\mathrm{R})$ Core(TM) i5-2400 CPU @ $3.10 \times 4 \mathrm{GHz}$ and 7.7 GiB of RAM. For the experiments, we consider two sets of instances as our test suite - Set $A$ consists of 10 classes of graphs with known optimal results [23], whereas Set $B$ consists of 70 instances of Harwell- Boeing (HB) graphs taken from the public domain Matrix Market library (available at https://math.nist.gov/MatrixMarket/data/Harwell-Boeing/) that are mostly used for the optimization problems in communication networks. Optimal results are not known for this latter set .

The classes of graphs in Set $A$ are listed in Table 1. In the second column of the table, the size of the graphs (i.e. number of nodes) is shown varying within the specified range. '\# inst' shows the number of instances generated for each

Table 1 Graphs in Set $A$

| Graphs | size | \# inst | optimal |
| :---: | :---: | :---: | :---: |
| $P t$ | 10 | 1 | 4 |
| $K_{1, n-2,1}$ | $[4,120]$ | 10 | 2, for $n \geq 4$ |
| $C_{n}$ | $[5,150]$ | 10 | $n-1$, for $n \geq 3$ |
| $W_{n}$ | $[5,1500]$ | 18 | 2, for $n \geq 4$ |
| $K_{n}$ | $[5,1400]$ | 17 | 2, for $n \geq 3$ |
| $S_{n}$ | $[10,1495]$ | 18 | - |
| $K_{n_{1}, n_{2}, \ldots, n_{k}}$ | $[8,1500]$ | 17 | 3, if $k=2, n_{1}, n_{2} \geq 2$ or $k \geq 3, n_{1} \neq 1$ |
|  |  | 2, if $k \geq 3, n_{1}=1$ |  |
| $T_{n}$ | $[10,1485]$ | 17 | $\left\lceil\frac{2 n}{3}\right\rceil+1$, for $n \geq 1$ |
| $P_{m} \times P_{n}$ | $[6,100]$ | 9 | $2\left\lfloor\frac{m}{2}\right\rfloor+1,2 \leq m \leq n$ |
| $($ small) |  |  |  |

| (small) |  |  |  |
| $T R_{m, n}$ | $[150,1500]$ | 9 | same as for $2 \leq m \leq n$ |
| (large) |  |  |  |

Table 2 Parameter tuning for ABC methods

| parameters | values tested for tuning | values used |
| :---: | :---: | :---: |
| $m_{1}$ | $25,50,100,150$ | 50 |
| $m_{2}$ | $25,50,100,150$ | 100 |
| $P_{b t s}$ | $0.75,0.80,0.85,0.90$ | 0.80 |
| $P_{\text {nbd }}$ | $0.90,0.95,0.98$ | 0.95 |
| iter $_{\text {limit }}$ | $50,100,150$ | 100 |

class. The last column gives the optimal values of each of the classes of graphs except Split graphs whose details are given in [23]. For the preliminary experiments, and to avoid the overtraining of the methods, a representative set of 10 HB graphs consisting of lund_a, lund_b, steam1, dwt361, bcsstm07, pores3, $d w t 592$, steam $2, f s \_680 \_1$ and saylr3 instances is considered as the training set.

To carry out the experiments, five independent trials are conducted for each of the three algorithms- ABC, ABC_Nbr and GVNS on each instance of the test suite. Considering that we reimplemented the ABC algorithm to target the MSSTP, we perform a preliminary experiment to adjust its parameters. Table 2 shows the values tested for the five search parameters of the method, and those that achieved the best results in a full-factorial design. We have empirically found that after 50,000 evaluations the ABC methods do not yield further improvements. We therefore set this value as the termination criterion in our experiments.

To investigate the performance of the construction heuristics used in generation of the initial solution in GVNS, a second experiment is conducted on the subset of representative instances. For this, five independent runs of GVNS are performed (a) using Max_degree_BFS (found to be the best construction heuristic among the five heuristics by our preliminary experiments aimed to compare their performance) only and (b) by selecting one of the five

Table 3 Comparison of neighborhood strategies in GVNS

|  | two_nbd | all_nbd |
| :---: | :---: | :---: |
| Stretch | 15.88 | $\mathbf{1 5 . 8 4}$ |
| gbest_time | 83.49 | $\mathbf{3 1 . 2 3}$ |
| $t_{c}$ | 428.10 | 451.37 |

construction heuristics (see Section 2) randomly. As no significant difference is found in the results obtained, random selection of construction heuristic is implemented in our method to have diverse initial solutions in different runs of GVNS.

The third preliminary experiment is conducted to analyse the performance of the neighborhood strategies used in GVNS to generate neighbors of a given solution. For this, GVNS is run (a) using two neighborhood strategies $\mathrm{NBHD}_{1}$ and $\mathrm{NBHD}_{2}$ only (referred as two_nbd) and (b) using all the neighborhood strategies (referred as all_nbd). Table 3 shows the average values of Stretch, gbest_time (time to attain global best solution) and $t_{c}$ (completion time) over five independent runs obtained by GVNS using both methods. From the results, it can be seen that the performance of GVNS is better when all the neighborhood strategies are incorporated as compared to using only two neighborhoods. Therefore, GVNS with all neighborhood strategies is used for the main experiments.

In our final preliminary experiment we study the order in which the neighborhoods are explored. In particular, we consider five different versions of our GVNS algorithm that only differ in the order in which the neighborhoods are scanned within the variable neighborhood template. We did not observe significant differences in the results and therefore we do not include the results of this experiment.

We now compare our method, set with the key strategies determined above, with the best methods identified in the literature. All the three algorithms give optimal results for Cycle graph, Diamond graph and Peterson graph (classes of Set $A$ ). The results of remaining classes obtained by the three algorithms are shown in Table 4. In the table, ' $O_{a}$ ' is the average of known optimal Stretch values over the number of instances corresponding to each class. ' $S \_T_{\text {min }}$ ' and ' $S_{-} T_{\text {avg }}$ ' show the minimum and average Stretch values respectively, obtained by the algorithms in 5 runs, while ' $t_{\text {avg }}$ ' shows the average execution time (in seconds) to attain the global best solution over same number of runs. '\#best' is the number of best solutions of $S_{-} T_{\min }$ among the three algorithms, and '\#opt' show the number of optimal values attained by these algorithms for the instances of Set $A$. It is to be noted here that the results are the averages of the values attained by the algorithms for each parameter (i.e $S_{-} T_{\text {min }}, S \_T_{a v g}, t_{a v g}$, \#best and \#opt) over the number of instances for each class of graphs. Table 5 presents the results obtained by these algorithms on HB graphs reporting the same parameters (except \#opt) as given in Table 4. Following result for general graphs [26] is used to compute the lower bound (LB) for the instances of HB graphs:

$$
\operatorname{Stretch}\left(G, S_{-} T^{*}\right) \geq \max _{\forall(u, w) \in A(G)} D_{G}^{\prime}(u, w)
$$

where, $D^{\prime}{ }_{G}(u, w)$ is the shortest distance between $u$ and $w$ in $G \backslash(u, w)$ and $S \_T^{*}$ is an optimal solution. It is observed that for the instances of this class lower bounds (optimal values) are attained by GVNS, ABC, and ABC_Nbr in 9,7 and 6 cases out of a total of 70 cases respectively. We have categorized HB graphs based on their sizes as small graphs $(|N| \leq 100)$, medium graphs (100 $<|N| \leq 500)$ and large graphs $(500<|N| \leq 1000)$ for a fairer comparison of mean values. In the tables, the results for which the performance of GVNS is better than that of ABC and ABC_Nbr are shown in bold. These comparisons consistently show that GVNS outperforms the other two methods, since GVNS attains optimal and best values in many more instances than ABC and ABC_Nbr. To complement the numerical analysis, comparison graphs depicting (a) minimum Stretch values, (b) average Stretch values and (c) average time taken by these algorithms over 5 runs for the large Rectangular Grids are shown respectively in Fig. 4(a), (b) and (c). Similar illustration is given for large HB graphs in Fig. 5. The comparison clearly indicates the superiority of GVNS over ABC and ABC_Nbr.

The results of GVNS, ABC and ABC_Nbr are compared statistically on all the instances of Set $A$ and $B$ using two-way ANOVA without repetition test with $5 \%$ level of significance for $S_{-} T_{\min }, S_{-} T_{a v g}$ and $t_{a v g}$. It shows that there is a significant difference among the mean values of $S_{-} T_{\min }$ over the three algorithms, whereas there is no significant difference among the mean values of $S_{-} T_{\text {avg }}$ of these algorithms. A Tukey's HSD test for pairwise comparison on $S_{-} T_{\text {min }}$ indicates that the three algorithms are significantly different from each other. Similar test done on the running times of the algorithms reveal that there is no significant difference between the mean values of $t_{\text {avg }}$ of ABC_Nbr and ABC , while the mean values of $t_{\text {avg }}$ are significantly different for the pairs (ABC, GVNS) and (ABC_Nbr, GVNS).

## 5 Conclusion

In this paper, a General Variable Neighborhood Search (GVNS) is proposed for MSSTP which uses the well known spanning tree algorithms for generating initial solutions. Six problem specific neighborhood techniques are designed which help in an exhaustive search of the solution space. Extensive experiments are conducted on various types of graphs in order to asses the performance of the proposed algorithm. Further, the results are compared with the adapted version of ABC (initially proposed for the tree $t$-spanner problem in the literature) and ABC_Nbr. Effectiveness of GVNS is clearly indicated through the results obtained by the three approaches in a majority of instances.

We learnt an interesting lesson from our testing that goes beyond the resolution of this specific problem. The variable neighborhood search template

|  | $S_{-} T_{\text {avg }}$ | $\mathbf{8 . 5 1}$ | $\mathbf{1 5 . 9 4}$ | $\mathbf{2 4 . 7 9}$ |
|  | $t_{\text {avg }}$ | $\mathbf{2 . 1 2}$ | $\mathbf{4 6 . 8 4}$ | $\mathbf{2 4 3 . 7 7}$ |
|  | \#best | $\mathbf{1 5}$ | $\mathbf{3 5}$ | $\mathbf{1 9}$ |

clearly benefits from a relatively large number of neighbors. We invite researchers in others problems to test this point to advance the knowledge of the methodology.

## Acknowledgment

The first author would like to thank University Grants Commission (UGC), India for providing RGNF fellowship [RGNF-2014-15-SC-UTT-74975] during the research. Rafael Martí is partially funded by the Spanish Ministry of Science and Innovation with grant ref. PGC2018-0953322-B-C21 MCIU/AEI/FEDERUE.
